Abstract

We study several anisotropic inflationary models and their implications for the observed violation of statistical isotropy in the CMBR data. In two of these models the anisotropy decays very quickly during the inflationary phase of expansion. We explicitly show that these models lead to violation of isotropy only for low $l = 2, 3$ multipoles to the theoretical models. Our primary aim is to fit the observed alignment of $l = 2, 3$ multipoles to the theoretical models. We use two measures, based on the power tensor, which contains information about the alignment of each multipole, to quantify the anisotropy in data. One of the measures uses the dispersion in eigenvalues of the power tensor. We also define another measure which tests the overall correlation between two different multipoles. We perturbatively compute these measures of anisotropy and fix the theoretical parameters by making a best fit to $l = 2, 3$ multipoles. We show that some of the models studied are able to consistently explain the observed violation of statistical isotropy.

1 Introduction

There exist many observations which suggest violation of the cosmological principle. These include dipole anisotropy in radio polarizations [1, 2], large scale alignment of optical polarizations [3], alignment of $l = 2, 3$ multipoles of the cosmic microwave background radiation [4–6], dipole anisotropy in distribution of radio galaxies [7] and cluster peculiar velocities [8]. Remarkably all of these indicate a preferred direction towards the Virgo cluster, close to the observed CMB dipole. This coincidence of diverse axes was first pointed out in [9, 10].

There also exist several other indications of violations of isotropy. These include dipole modulations to CMB including north-south ecliptic power asymmetry [11–17], quadrupolar power modulation to CMB [16, 18–20], dipole anisotropy in galaxy distribution [21], and parity violation in the CMB data [22, 23] and in the handedness of the spiral galaxies [24]. The indications for a preferred direction in diverse data sets have motivated many theoretical studies of inflationary models which violate statistical isotropy and homogeneity, giving rise to

a direction dependent power spectrum [18, 25–36]. Anisotropic inflation is likely to lead to observable effects in the CMBR [37].

It is well accepted that the observed Universe is neither isotropic nor homogeneous at early times. It may evolve into a de Sitter space as it expands in presence of a positive cosmological constant. This has been explicitly established for Bianchi models, which represent a homogeneous and anisotropic Universe. An anisotropic Bianchi model is expected to become isotropic within a time scale of order $\sqrt{\frac{3}{\Lambda}}$ during the early stages of inflation [38]. It was pointed out in [39], that even this brief early phase of anisotropic expansion can lead to violations of statistical isotropy in the current era. It was shown that for a wide range of parameters, modes generated during the anisotropic inflationary period can re-enter the horizon at recent times and hence affect observations. For some parameter range they may re-enter even before decoupling of radiation from matter [39]. In the current paper we shall show that the anisotropic modes arising during the very early phase of inflation can consistently explain the alignment of CMB quadrupole and octopole. We point out that our explanation is within the framework of the inflationary Big Bang cosmology.

There exist several techniques to study the violation of statistical isotropy in the CMB data. These include bipolar spherical harmonics [40, 41], the power tensor [9, 42], multipole vectors [5] etc. Here we shall use the power tensor, which is defined by,

$$A_{ij}(l) = \frac{1}{l(l+1)} \sum_{m, m', m''} \langle lm | J_i | lm' \rangle \langle lm'' | J_j | lm \rangle a_{lm'} a_{lm''}^* \quad (1)$$

where a_{lm} are the standard harmonic coefficients of the temperature anisotropy, $\Delta T(\hat{n})/T$, and J_i are the angular momentum operators in spin- l representation. This tensor is a second rank real symmetric matrix. Its eigenvectors define an invariant frame for each multipole and the corresponding eigenvalues yield the power along each of these vectors. For a given multipole, the eigenvector associated with the largest eigenvalue of the power tensor is called the principal eigenvector (PEV). This defines the preferred direction for that multipole [9, 42]. Statistical isotropy implies that the two point correlations of the harmonic coefficients obey,

$$\langle a_{lm} a_{l'm'}^* \rangle = \delta_{ll'} \delta_{mm'} C_l \quad (2)$$

where C_l is the power spectrum and the angular brackets denote an ensemble average. For the power tensor, this implies,

$$\langle A_{ij}(l) \rangle = \frac{C_l}{3} \delta_{ij}. \quad (3)$$

In the case of an anisotropic background metric,

$$\langle a_{lm} a_{l'm'}^* \rangle = C_{ll' mm'}, \quad (4)$$

i.e. the correlations are not diagonal as in the isotropic case. This will imply that, in contrast to Eq. 3, the power tensor is not proportional to δ_{ij} . Furthermore it will also generate correlations in the power tensor for different multipoles.

The alignment of the CMB quadrupole and octopole can be tested in the power tensor approach by determining the corresponding PEVs [9, 42, 43]. These

are found to be aligned very closely with one another. In the 7 year WMAP data release, the significance of alignment is found to be better than 4σ CL in the ILC map [43]. The multipoles, $l = 2, 3$, by themselves, however, do not give any indication of violation of statistical isotropy. The hot and cold spots, both for $l = 2$ and $l = 3$ do lie roughly in a single plane. However the effect is not statistically significant. It is only the alignment of the two multipoles which is significant.

In our theoretical approach we work in a preferred coordinate system with the preferred axis aligned along the PEV corresponding to $l = 2$. We use two different approaches to test for alignment. In one approach we determine the PEV for each multipole and then test for its alignment. In the second approach we follow a blind procedure which directly tests the overlap of the two power tensors. The overlap is defined as the trace of the matrix $\langle A^+(l)A(l') \rangle_{ij}$. We may express this ensemble average as,

$$\begin{aligned} \langle A^+(l)A(l') \rangle_{ij} &= \sum_k \langle A_{ki}(l)^* A_{kj}(l') \rangle \\ &= \frac{1}{N(l)N(l')} \sum_k \sum_{m_n=-l}^l \sum_{m'_n=-l'}^{l'} \langle lm_1|J_k|lm_2 \rangle^* \langle lm_3|J_i|lm_1 \rangle^* \\ &\quad \langle l'm'_1|J_k|l'm'_2 \rangle \langle l'm'_3|J_j|l'm'_1 \rangle \langle a_{lm_2}^* a_{lm_3} a_{l'm'_2} a_{l'm'_3}^* \rangle. \end{aligned} \quad (5)$$

where the normalization $N(l) = l(l+1)$. Here on the right hand side the subscript n takes values 1, 2, 3, i.e. the sums are over $m_1, m_2, m_3, m'_1, m'_2, m'_3$. The corresponding statistic is defined as,

$$S_{ll'} = \frac{3}{C_l C_{l'}} \text{Tr} \langle A^+(l)A(l') \rangle, \quad (6)$$

For the isotropic case, the expectation value on the right hand side factorizes and we obtain,

$$S_{ll'}(\text{isotropic}) = 1. \quad (7)$$

Here we shall only be interested in the case $l' = l+1$ and hence use the statistic,

$$S_l = \frac{3}{C_l C_{l+1}} \text{Tr} \langle A^+(l)A(l+1) \rangle. \quad (8)$$

The blind approach has the advantage that it tests the overall correlation of the two multipoles rather than testing a specific feature. Hence it does not suffer from the criticism of being an a posteriori statistic [20]. As expected, this statistic leads to a smaller significance of alignment between $l = 2, 3$.

The power spectrum $P(k)$ for the primordial density perturbation $\delta(k)$ is defined as

$$\langle \delta(k)\delta^*(k') \rangle = P(k)\delta^3(k-k') \quad (9)$$

where $\delta(k)$ is the Fourier amplitude of the density inhomogeneities,

$$\frac{\delta\rho(x)}{\rho(x)} = \frac{1}{(2\pi)^3} \int \delta(k) e^{-i\vec{k}\cdot\vec{x}} d^3k. \quad (10)$$

In the case of a homogeneous and isotropic FRW metric, the fluctuations are statistically isotropic and the primordial power spectrum $P(k)$ depends only on

the magnitude of the wave vector $\vec{k}$. However, in the case of anisotropic models, which we shall consider in this paper, it will also depend on the direction. The direction dependent contribution to $P(k)$ has been obtained in a particular anisotropic model in Ref. [18]. Here we examine this model as well as two other models of anisotropic inflation.

2 Anisotropic Metric

We consider three different anisotropic metrics. The axis of anisotropy is taken to be the z -axis. The first model may be expressed as,

$$ds^2 = dt^2 - 2\sqrt{\sigma}dzdt - a^2(t)(dx^2 + dy^2 + dz^2) \quad \text{Model I} \quad (11)$$

where $a(t)$ is the scale factor and σ is the anisotropic parameter which controls deviation from statistical isotropy. The second model we consider is same as the one used in [18]. The corresponding metric is given by,

$$ds^2 = dt^2 - a^2(t)dx_{\perp}^2 - b^2(t)dz^2 \quad \text{Model II} \quad (12)$$

where $dx_{\perp}^2 = dx^2 + dy^2$. This model is anisotropic throughout inflation. The third model is a modification of this model such that the anisotropic term becomes insignificant after one efold. The line elements may be expressed as,

$$ds^2 = dt^2 - a_1^2(t)(dx^2 + dy^2) - a_2^2(t)dz^2 \quad \text{Model III} \quad (13)$$

where $a_2(t) = a_1(t) + \sigma$, σ being a constant, independent of time. We also define, $\bar{a}(t) = (a_1^2(t)a_2(t))^{\frac{1}{3}}$.

Here we shall present the calculation of the alignment between multipoles for the case of model I in detail. The calculation for model II and III proceeds along the same line and for these models we only give the final results. We shall treat the anisotropic term perturbatively, following the treatment of [18]. For models I and III this term is expected to be significant only at very early times. For model II, this term would contribute during the entire inflationary period. In all the models, the anisotropy parameter may be fixed by fitting the data for $l = 2, 3$ multipoles. The reliability of perturbation theory will depend on the magnitude of this parameter.

The components of the Einstein tensor for the perturbed metric corresponding to model I are

$$G_{00} = \frac{a(t)[5\sigma + 3a^2(t)]\dot{a}^2(t) - 2\sigma[\sigma + a^2(t)]\ddot{a}(t)}{a(t)(\sigma + a^2(t))^2} \quad (14)$$

$$G_{03} = -\sqrt{\sigma} \frac{[3\sigma + a^2(t)]\dot{a}^2(t) + 2a(t)[\sigma + a^2(t)]\ddot{a}(t)}{[\sigma + a^2(t)]^2} \quad (15)$$

$$G_{11} = -a^2(t) \frac{[3\sigma + a^2(t)]\dot{a}^2(t) + 2a(t)[\sigma + a^2(t)]\ddot{a}(t)}{[\sigma + a^2(t)]^2} \quad (16)$$

$$G_{30} = G_{03} \quad (17)$$

$$G_{11} = G_{22} = G_{33}. \quad (18)$$

The perfect fluid energy momentum tensor is defined as,

$$T_{\mu\nu} = (\rho + P)u_{\mu}u_{\nu} - Pg_{\mu\nu}. \quad (19)$$

This leads to the following off-diagonal terms,

$$T_{03} = T_{30} = -\rho\sqrt{\sigma}. \quad (20)$$

The Einstein equations, to zeroth order in the anisotropic parameter $\sqrt{\sigma}$, are given by,

$$\left(\frac{\dot{a}}{a}\right)^2 + 2\frac{\ddot{a}}{a} = -8\pi GP \quad (21)$$

$$3\left(\frac{\dot{a}}{a}\right)^2 = 8\pi G\rho \quad (22)$$

where the dot refers to the derivative with respect to the cosmic time t . Hence with $P = -\rho$ we get standard inflationary solution,

$$a(t) = a_I e^{Ht} \quad (23)$$

where H is the Hubble constant during inflation.

3 Quantization of field and power spectrum

In this section we discuss the quantization of the massless scalar field [44] and obtain the power spectrum perturbatively to first order in the anisotropy parameter, $\sqrt{\sigma}$. The action may be written as,

$$S_\phi = \int d^4x \mathcal{L} \quad (24)$$

where the Lagrangian density,

$$\mathcal{L} = \frac{1}{2}\sqrt{-g}g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi. \quad (25)$$

The scalar field $\phi(x, t)$ is quantized in the standard manner by expanding in Fourier modes,

$$\phi_I(x, t) = \int \frac{d^3k}{(2\pi)^3} \left(e^{i\vec{k}\cdot\vec{x}} \phi_k(t) a_k + e^{-i\vec{k}\cdot\vec{x}} \phi_k^*(t) a_k^\dagger \right). \quad (26)$$

The creation and annihilation operators a_k^+ and a_k satisfy the commutation relation $[a_k, a_{k'}^+] = (2\pi)^3 \delta(k - k')$. The Euler-Lagrange equation of motion,

$$\frac{1}{\sqrt{-g}}\partial_\nu(g^{\mu\nu}\sqrt{-g}\partial_\mu\phi) = 0, \quad (27)$$

for the isotropic FRW metric reduces to,

$$\ddot{\phi} + 3H\dot{\phi} - \frac{\nabla^2}{a^2}\phi = 0. \quad (28)$$

In conformal time, this can be written as,

$$v_k'' + \left(k^2 - \frac{a''}{a}\right)v_k = 0, \quad (29)$$

where, $v_k = a\phi_k$ and $' = \frac{d}{d\eta}$ denotes the derivative with respect to the conformal time. The solution to the unperturbed equations, $\phi_k^0(\eta)$, is given by,

$$\phi_k^0(\eta) = \frac{H}{\sqrt{2k}} \left(\frac{i}{k} - \eta \right) \exp(-ik\eta). \quad (30)$$

The Hamiltonian in interaction-picture is found to be

$$H_I = \int d^3x \sqrt{\sigma} \left(\frac{d\phi_I(x, \eta)}{d\eta} \frac{d\phi_I(x, \eta)}{dz} \right). \quad (31)$$

The two point correlations, to first order, are given by, [18, 45],

$$\begin{aligned} \langle \phi(x_1, t) \phi(x_2, t) \rangle &\equiv \langle \phi_I(x_1, t) \phi_I(x_2, t) \rangle + \\ &i \int_0^t dt' \langle [H_I(t'), \phi_I(x_1, t) \phi_I(x_2, t)] \rangle. \end{aligned} \quad (32)$$

This leads to,

$$\langle \phi(x_1, t) \phi(x_2, t) \rangle = \int \frac{d^3k}{(2\pi)^3} \exp \left[i\vec{k} \cdot (\vec{x}_1 - \vec{x}_2) \right] [P_{iso}(k) + k_z \Delta P(k)] \quad (33)$$

where

$$P_{iso}(k) \simeq |\phi_k^{(0)}(\eta)|^2 \quad (34)$$

and

$$\Delta P(k) = -2\sqrt{\sigma} \int_{\frac{-1}{Ha_I}}^{\eta} a(\eta') d\eta' \left[\frac{d\phi_k^0(\eta')}{d\eta'} \phi_k^{0*}(\eta) \phi_k^0(\eta') \phi_k^{0*}(\eta) + c.c \right]. \quad (35)$$

Here we have used,

$$\eta = \int \frac{dt}{a(t)} = -\frac{1}{Ha_I} e^{-Ht}. \quad (36)$$

The complete expression for $\Delta P(k)$ is given by,

$$\begin{aligned} \Delta P(k) &= P_{iso}(k) \left(\frac{\sqrt{\sigma}}{k} \right) \left\{ H\eta(2 + k^2\eta^2) \right. \\ &+ \frac{1}{a_I} (-1 - 3a_I H\eta + k^2\eta^2) \cos \left[2k \left(\frac{1}{a_I H} + \eta \right) \right] \\ &\left. - \frac{1}{2a_I k} [4k^2\eta + 3a_I H(-1 + k^2\eta^2)] \sin \left[2k \left(\frac{1}{a_I H} + \eta \right) \right] \right\} \end{aligned} \quad (37)$$

Here we assume that the universe was anisotropic at early times. The perturbations which are generated during the early anisotropic phase may re-enter the horizon during matter or radiation dominated phases. These modes crossed the horizon very early during inflation. This implies $k \sim a_I H$. Taking the limit $|k\eta| \ll 1$, we find that,

$$P_{iso}(k) \simeq \frac{H^2}{2k^3}, \quad (38)$$

$$\Delta P(k) = - \left(\frac{\sqrt{\sigma}}{a_I} \right) \left(\frac{H^2}{2k^4} \right) \left[\cos \left(\frac{2k}{a_I H} \right) - \left(\frac{3Ha_I}{2k} \right) \sin \left(\frac{2k}{a_I H} \right) \right]. \quad (39)$$

Finally, the modified direction dependent power spectrum is given by,

$$P'(k) = P_{iso}(k)[1 + (\hat{k} \cdot \hat{z})g(k)] \quad \text{Model I} \quad (40)$$

where $\hat{k}$ is the unit vector along the direction of k , $\hat{z}$ is the unit vector along the preferred direction and the function $g(k)$ is defined as,

$$g(k) = -\frac{\sqrt{\sigma}}{a_I} \left[\cos\left(\frac{2k}{a_I H}\right) - \left(\frac{3H a_I}{2k}\right) \sin\left(\frac{2k}{a_I H}\right) \right]. \quad (41)$$

The corresponding results in model II have already been obtained in Ref. [18]. The power spectrum can be expressed as,

$$P'(k) = P_{iso}(k) \left[1 + g(k)(\hat{k} \cdot \hat{n})^2 \right] \quad \text{Model II} \quad (42)$$

where $\hat{n} = (0, 0, 1)$ in the notation of Ref. [18]. The function, $g(k)$, at the end of inflation (time t_*) is given by,

$$g(k) = \frac{9}{2} \epsilon_H \log \left[\frac{q(t_*)}{\bar{H}} \right], \quad (43)$$

$\bar{H} = \frac{1}{3}(2H_a + H_b)$ and the physical wavelength $q(t_*) = \frac{k}{a(t_*)}$. The anisotropic parameter ϵ_H is defined as

$$\epsilon_H = \frac{2}{3} \left(\frac{H_b - H_a}{\bar{H}} \right). \quad (44)$$

Here we have neglected the perturbative correction to the isotropic power spectrum.

In the case of model III, the Hamiltonian in interaction picture is

$$H_I(t) = - \int d^3x \frac{1}{2} \left\{ (\bar{a}(t) - a_2(t)) \left[\left(\frac{d\phi}{dx} \right)^2 + \left(\frac{d\phi}{dy} \right)^2 \right] + \left(\bar{a}(t) - \frac{a_1^2(t)}{a_2(t)} \right) \left(\frac{d\phi}{dz} \right)^2 \right\}. \quad (45)$$

The two point correlation function is found to be,

$$\langle \phi(x_1, t) \phi(x_2, t) \rangle = \int \frac{d^3k}{(2\pi)^3} \exp \left[i \vec{k} \cdot (\vec{x}_1 - \vec{x}_2) \right] [P'_{iso}(k) + k_z^2 \Delta P(k)] \quad (46)$$

where

$$\Delta P(k) \simeq -2\sigma \int_{\frac{-1}{H a_I}}^{\eta} a(\eta') d\eta' \left[2 \text{Im} \left(\phi_k^0(\eta')^2 \phi_k^{0*}(\eta')^2 \right) \right]. \quad (47)$$

The modified power spectrum is given by,

$$P'(k) = P'_{iso}(k) \left[1 + (\hat{k} \cdot \hat{z})^2 g(k) \right], \quad (48)$$

where,

$$g(k) = -\frac{\sigma}{a_I k} \left[k \cos\left(\frac{2k}{a_I \bar{H}}\right) - \frac{5}{2} a_I \bar{H} \sin\left(\frac{2k}{a_I \bar{H}}\right) + 2 a_I \bar{H} \text{Si}\left(\frac{2k}{a_I \bar{H}}\right) \right] \quad (49)$$

with

$$\text{Si}(x) \equiv \int_0^x dx' \frac{\sin x'}{x'}. \quad (50)$$

Here the isotropic power spectrum, $P'_{iso}(k)$, includes a perturbative correction to $P_{iso}(k)$. It is given by,

$$P'_{iso}(k) = P_{iso}(k) \left[1 - \frac{g(k)}{3} \right] \quad (51)$$

4 Effect of the power spectrum on the Cosmic Microwave Background

The temperature perturbation can be decomposed in terms of spherical harmonics, $Y_{lm}(\hat{p})$, as follows,

$$\frac{\delta T}{T}(\vec{x}, \hat{p}, \eta) = \sum_{l=1}^{\infty} \sum_{m=-l}^l a_{lm} Y_{lm}(\hat{p}). \quad (52)$$

This temperature anisotropy $\frac{\delta T}{T}$ can be related to the primordial density fluctuations as :

$$\frac{\delta T}{T}(\hat{p}) = \int dk \sum_l \frac{2l+1}{4\pi} (-i)^l P_l(\hat{k} \cdot \hat{p}) \delta(k) \Theta_l(k) \quad (53)$$

where P_l is the Legendre polynomial of order l and $\Theta_l(k)$ is the transfer function which correlates initial fluctuations to the observed temperature anisotropies. The expansion coefficients a_{lm} can be calculated using,

$$a_{lm} = \int d\Omega Y_{lm}^*(\hat{p}) \frac{\delta T}{T}(\vec{x}, \hat{p}, \eta). \quad (54)$$

We now compute the two point correlation function of a_{lm} 's using the directional dependent power spectrum. We have,

$$\langle a_{lm} a_{l'm'}^* \rangle = \langle a_{lm} a_{l'm'}^* \rangle_{iso} + \langle a_{lm} a_{l'm'}^* \rangle_{aniso} \quad (55)$$

where the first term corresponds to the isotropic case. It is given by

$$\langle a_{lm} a_{l'm'}^* \rangle_{iso} = \delta_{ll'} \delta_{mm'} \int_0^{\infty} k^2 dk P_{iso}(k) \Theta_l^2(k). \quad (56)$$

The second term which contains departures from statistical isotropy is given by,

$$\langle a_{lm} a_{l'm'}^* \rangle_{aniso} = (-i)^{l-l'} \xi_{lm;l'm'} \int_0^{\infty} k^2 dk P_{iso}(k) g(k) \Theta_l(k) \Theta_{l'}(k) \quad (57)$$

where we have used the spherical components of the unit vector n as

$$n_+ = -\left(\frac{n_x - in_y}{\sqrt{2}}\right), n_- = \left(\frac{n_x + in_y}{\sqrt{2}}\right), n_0 = n_z. \quad (58)$$

The constant $\xi_{lm;l'm'}$, which encodes the correlation between different multipoles, is defined as

$$\begin{aligned}\xi_{lm;l'm'} &= \sqrt{\frac{4\pi}{3}} \int d\Omega_k (Y_{lm}(\hat{k}))^* Y_{l'm'}(\hat{k}) \\ &\quad \times \left(n_+ Y_1^1(\hat{k}) + n_- Y_1^{-1}(\hat{k}) + n_0 Y_1^0(\hat{k}) \right) \\ &= n_+ \xi_{lm;l'm'}^+ + n_- \xi_{lm;l'm'}^- + n_0 \xi_{lm;l'm'}^0,\end{aligned}\quad (59)$$

where,

$$\begin{aligned}\xi_{lm;l'm'}^+ &= \sqrt{\frac{1}{2}} \delta_{m',m-1} \left[-\sqrt{\frac{(l-m+1)(l-m+2)}{(2l+1)(2l+3)}} \delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l+m-1)(l+m)}{(2l+1)(2l-1)}} \delta_{l',l-1} \right]\end{aligned}\quad (60)$$

$$\begin{aligned}\xi_{lm;l'm'}^- &= \sqrt{\frac{1}{2}} \delta_{m',m+1} \left[-\sqrt{\frac{(l+m+1)(l+m)}{(2l+1)(2l+3)}} \delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l-m-1)(l-m)}{(2l+1)(2l-1)}} \delta_{l',l-1} \right]\end{aligned}\quad (61)$$

$$\begin{aligned}\xi_{lm;l'm'}^0 &= \delta_{m',m} \left[\sqrt{\frac{(l-m+1)(l+m+1)}{(2l+1)(2l+3)}} \delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l-m)(l+m)}{(2l+1)(2l-1)}} \delta_{l',l-1} \right].\end{aligned}\quad (62)$$

Similarly, using $a_{lm} = (-1)^m a_{l-m}^*$, we obtain,

$$\langle a_{lm} a_{l'm'} \rangle_{iso} = (-1)^{m'} \delta_{l,l'} \delta_{m,-m'} \int_0^\infty k^2 dk P_{iso}(k) \Theta_l^2(k) \quad (63)$$

and

$$\langle a_{lm} a_{l'm'} \rangle_{aniso} = (-1)^{m'} (-i)^{l-l'} \bar{\xi}_{lm;l'-m'} \int_0^\infty k^2 dk P_{iso}(k) g(k) \Theta_l(k) \Theta_{l'}(k). \quad (64)$$

We express $\bar{\xi}_{lm;l'-m'}$ as,

$$\bar{\xi}_{lm;l'-m'} = n_+ \bar{\xi}_{lm;l'-m'}^+ + n_- \bar{\xi}_{lm;l'-m'}^- + n_0 \bar{\xi}_{lm;l'-m'}^0, \quad (65)$$

where,

$$\begin{aligned}\bar{\xi}_{lm;l'-m'}^+ &= \sqrt{\frac{1}{2}}\delta_{m',-(m-1)} \left[\sqrt{\frac{(l-m+1)(l-m+2)}{(2l+1)(2l+3)}}\delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l+m-1)(l+m)}{(2l+1)(2l-1)}}\delta_{l',l-1} \right]\end{aligned}\quad (66)$$

$$\begin{aligned}\bar{\xi}_{lm;l'-m'}^- &= \sqrt{\frac{1}{2}}\delta_{m',-(m+1)} \left[\sqrt{\frac{(l+m+1)(l+m+2)}{(2l+1)(2l+3)}}\delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l-m-1)(l-m)}{(2l+1)(2l-1)}}\delta_{l',l-1} \right]\end{aligned}\quad (67)$$

$$\begin{aligned}\bar{\xi}_{lm;l'-m'}^0 &= \delta_{m',-m} \left[\sqrt{\frac{(l-m+1)(l+m+1)}{(2l+1)(2l+3)}}\delta_{l',l+1} \right. \\ &\quad \left. + \sqrt{\frac{(l-m)(l+m)}{(2l+1)(2l-1)}}\delta_{l',l-1} \right].\end{aligned}\quad (68)$$

Computing the trace of $\langle A^+(l)A(l+1) \rangle$, we find

$$\begin{aligned}Tr\langle A^+(l)A(l+1) \rangle &= \frac{1}{4l(l+1)^2(l+2)} \sum_{m_i=-l}^l \left[d^+(l, m_1)d^-(l+1, m_5)\delta_{m_2, m_1+1}\delta_{m_4, m_5-1} \right. \\ &\quad \left. + d^-(l, m_1)d^+(l+1, m_5)\delta_{m_2, m_1-1}\delta_{m_4, m_5+1} + 2m_1m_5\delta_{m_1, m_2}\delta_{m_4, m_5} \right] \\ &\quad \times \left[d^+(l, m_3)d^-(l+1, m_4)\delta_{m_1, m_3+1}\delta_{m_6, m_4-1} + d^-(l, m_3)d^+(l+1, m_4) \right. \\ &\quad \left. \delta_{m_1, m_3-1}\delta_{m_6, m_4+1} + 2m_3m_4\delta_{m_1, m_3}\delta_{m_6, m_4} \right] \times \\ &\quad \left[\delta_{m_2, m_3}\delta_{m_5, m_6} \int_0^\infty k^2 dk P_{iso}(k) \Theta_l^2(k) \int_0^\infty k^2 dk P_{iso}(k) \Theta_{l+1}^2(k) \right. \\ &\quad \left. + \left(\bar{\xi}_{lm_2; (l+1)m_6} \bar{\xi}_{lm_3; (l+1)m_5}^* + \xi_{lm_2; (l+1)m_5} \xi_{lm_3; (l+1)m_6}^* \right) \times \right. \\ &\quad \left. \left(\int_0^\infty k^2 dk P_{iso}(k) g(k) \Theta_l(k) \Theta_{l+1}(k) \right)^2 \right]\end{aligned}\quad (69)$$

where we defined $d^+(l, m) = \sqrt{(l-m)(l+m+1)}$ and $d^-(l, m) = \sqrt{(l+m)(l-m+1)}$. Note that the sum in the above equation is over m_i , $i = 1, 2, \dots, 6$. Here we take the transfer function for large scales as $\Theta_l(k) = \frac{1}{3}J_l[k(\eta_0 - \eta_d)]$, where η_0 is the conformal time today and η_d is the conformal time at last scattering. Since $\eta_d \ll \eta_0$ we take $J_l[k(\eta_0 - \eta_d)] \approx J_l[k\eta_0]$. It is convenient to define, $x = k\eta_0$. In terms of x the function $g(k)$ in Eq. 41 may be expressed as,

$$g(x) = -\frac{\sqrt{\sigma}}{a_I} \left[\cos\left(\frac{2x}{\eta_0 a_I H}\right) - \frac{3H\eta_0 a_I}{2x} \sin\left(\frac{2x}{\eta_0 a_I H}\right) \right]. \quad (70)$$

The integral in Eq. 69 involves an oscillatory functions of x . It is clear that for large l the integral will get contributions from relatively large values of k . For sufficiently large k the integral will be damped due to oscillations in $g(x)$. Hence the correlations between different l are expected to be small for large l .

4.1 Models II and III

For models II and III the constant $\xi_{lm;l'm'}$ is the same as in [18] and is given by

$$\begin{aligned}\xi_{lm;l'm'} &= \frac{4\pi}{3} \int d\Omega_k (Y_{lm}(\hat{k}))^* Y_{l'm'}(\hat{k}) \\ &\quad \times \left(n_+ Y_1^1(\hat{k}) + n_- Y_1^{-1}(\hat{k}) + n_0 Y_1^0(\hat{k}) \right)^2 \\ &= n_+^2 \xi_{lm;l'm'}^{++} + n_-^2 \xi_{lm;l'm'}^{--} + 2n_+ n_- \xi_{lm;l'm'}^{+-} + 2n_+ n_0 \xi_{lm;l'm'}^{+0} \\ &\quad + 2n_- n_0 \xi_{lm;l'm'}^{-0} + n_0^2 \xi_{lm;l'm'}^{00} .\end{aligned}\quad (71)$$

For $l = l'$ the contributing terms of these coefficients are

$$\xi_{lm;l'm'}^{--} = -\delta_{m',m+2} \frac{\sqrt{(l^2 - (m+1)^2)(l+m+2)(l-m)}}{(2l+3)(2l-1)} \quad (72)$$

$$\xi_{lm;l'm'}^{--} = \xi_{l'm';lm}^{++} \quad (73)$$

$$\xi_{lm;l'm'}^{+-} = -\delta_{m',m} \frac{(l^2 + m^2 + l - 1)}{(2l-1)(2l+3)} \quad (74)$$

$$\xi_{lm;l'm'}^{-0} = -\frac{1}{\sqrt{2}} \delta_{m',m+1} \frac{(2m+1)\sqrt{(l+m+1)(l-m)}}{(2l-1)(2l+3)} \quad (75)$$

$$\xi_{lm;l'm'}^{+0} = -\xi_{l'm';lm}^{-0} \quad (76)$$

$$\xi_{lm;l'm'}^{00} = \delta_{m,m'} \frac{(2l^2 + 2l - 2m^2 - 1)}{(2l-1)(2l+3)} \quad (77)$$

Following [18] we set, $|\log\left(\frac{q(t_*)}{H}\right)| \simeq 60$. Hence, $g(k) = g_* = \frac{9}{2}\epsilon_H \times 60$. The ensemble average of the power tensor is given by,

$$\begin{aligned}\langle A_{ij}(l) \rangle &= \frac{1}{l(l+1)} \sum_{mm'm''} \langle lm|J_i|lm' \rangle \langle lm''|J_j|lm \rangle \\ &\quad \times \left[\langle a_{lm'} a_{lm''}^* \rangle_{iso} + \langle a_{lm'} a_{lm''}^* \rangle_{aniso} \right]\end{aligned}\quad (78)$$

In this model we find that $\langle A_{ij}(l) \rangle \neq \frac{C_l}{3} \delta_{ij}$. In the preferred coordinate system we obtain a diagonal matrix with the component corresponding to the preferred direction different from the other two.

5 Results

We first give the numerical results for model I. In this case we use the statistic S_l (Eq. 8), in order to test the correlation between different multipoles. As explained in the introduction, this tests the overall correlation of the two multipoles rather than testing a particular aspect, such as the alignment of their

principal eigenvectors. For an isotropic model, this statistic takes the value unity. We have explicitly verified this by using randomly generated CMB data. Furthermore the anisotropic term gives zero contribution to C_l in this model. The value of this statistic for the observed CMB data is given in the second column in Table 1. Here the results are presented for seven year WMAP data. We have checked that the nine year data also gives nearly identical results. The fourth column in the table gives the significance or P-value, i.e. the probability that the correlation seen in data arises as a random fluctuation in a statistically isotropic sample. This is computed by comparing the data statistic with 4000 random realizations of CMBR based on the Λ CDM model. We find that this statistic also indicates a significant correlation between $l = 2$ and $l = 3$ multipoles but doesn't lead to significant result for other multipoles. This agrees with earlier results which show a very strong alignment of the principal eigenvectors for $l = 2, 3$ [43] and a relatively mild effect for remaining multipoles [42].

The theoretically computed values of S_l for model I are given in the third column of Table 1. Here we have taken the anisotropy parameter $\sqrt{\sigma'} = \frac{\sqrt{\sigma}}{a_I} = 1.73$ in order to fit the observed S_l for $l = 2, 3$. We also set $\frac{2}{\eta_0 a_I H} = \frac{1}{2}$. If we choose a smaller value for this parameter, we shall obtain larger correlations for larger values of l . This choice of parameters fits the observations, as shown in Table 1. Our theoretical results match the data for $(l, l+1) \geq (3, 4)$ in the sense that neither the observed nor the theoretical values indicate significant correlation. We do not expect to obtain an exact match since the observed values are statistical in nature. Assuming that statistical isotropy is valid for $l \geq 4$, we expect that each of these multipoles would be aligned randomly and hence their correlations are expected to be small and take random values.

$(l, l+1)$	$S_l(\text{Data} - \text{value})$	$\text{Theoretical} - \text{value}$	$P - \text{value}$
(2,3)	1.487	1.487	0.005
(3,4)	0.696	1.279	0.969
(4,5)	1.030	1.127	0.416

(8,9)	1.007	1.013	0.458
(9,10)	1.050	1.021	0.227
(10,11)	0.989	1.019	0.568
(11,12)	0.934	1.001	0.849
(12,13)	0.886	1.003	0.968

Table 1: Comparison of the observed and theoretical results for model I. In column 2 and 3 we show the observed and theoretical values of the statistic S_l . The significance or P-value of the observed statistic is shown in column 4.

We point out that the contribution due to the anisotropic term is relatively small compared to unity, obtained with an isotropic model. Hence we expect perturbation theory to be qualitatively reliable. The maximum contribution is found to be 0.487 for the case of $l = (2, 3)$. We expect higher order corrections of the order of $(0.487)^2$, roughly about 25%.

We next describe the results corresponding to model II. In this case the

metric is anisotropic during the entire inflationary period. Hence we expect that all the modes, independent of the values of k , would violate isotropy and lead to alignment among CMB multipoles of arbitrary l values. In this case we compute the principal eigenvectors of the power tensor of each multipole. For each l we expect two equal eigenvalues. The third eigenvalue is found to be larger than these two eigenvalues for negative values of the anisotropy parameter ϵ_H . Hence, in this case, the principal eigenvector would align with the preferred (z) axis. We fix the value of ϵ_H by demanding that the theoretical and observed values for dispersion in the eigenvalues match with one another. A useful measure for dispersion is the power entropy [42]. Let λ_a , $a = 1, 2, 3$ represent the three eigenvalues of the power tensor. As discussed in [42], these eigenvalues are positive. We define the normalized eigenvalues

$$\tilde{\lambda}_a = \frac{\lambda_a}{\sum_i \lambda_i} \quad (79)$$

The power entropy, $S_P(l)$, may be expressed as,

$$S_P(l) = - \sum_a \tilde{\lambda}_a \log \tilde{\lambda}_a \quad (80)$$

$S_P(l)$ can take values in the range 0 to $\log 3$, with 0 being the value for maximal dispersion and, hence, anisotropy. In the CMB data sample, the value of $S_P(l)$ for any l deviates from the perfectly isotropic limit of $\log 3$ due to cosmic variance. The cosmic variance becomes small for large l . Hence, as expected, the observed value of $S_P(l)$ approaches $\log 3$ for large l [42]. We compute the power entropy expected for an isotropic sample by using 4000 randomly generated CMB data samples. Let $S_P(l, data)$ and $S_P(l, mean)$ denote, respectively, the power entropy of the observed CMB data and the mean of random samples. We attribute the difference $\Delta S_P(l) = S_P(l, data) - S_P(l, mean)$ to the contribution due to the anisotropic term. The theoretical estimate of $\Delta S_P(l)$ is, therefore, equal to $\Delta S_{P,th}(l) = S_{P,th} - \log 3$. Here $S_{P,th}$ is computed using the mean power tensor given in Eq. 78 and we subtract $\log 3$ since that is the value obtained in the limit of perfect isotropy.

For $l = 2, 3$ we find that, $\Delta S_P(2) = -0.0056$ and $\Delta S_P(3) = -0.064$ using the 9 year WMAP data. Similar results are obtained for 7 year data. For $l = 2$ the observed value is very close to that expected in an isotropic model. For $l = 3$ the deviation is larger but still less than 1σ . Hence the dispersion in eigenvalues for the observed data is not statistically significant for $l = 2$ or $l = 3$. We nevertheless fix the value of anisotropy parameters in model II so as to obtain a best fit to ΔS_P for $l = 2, 3$ by minimizing the square error. In future it might be more appropriate to make a global fit to the CMBR data in order to fix the parameters of this model. The best fit is obtained for $\epsilon_H = -0.0054$, which leads to $\Delta S_{P,th} = -0.034$ and root mean square error equal to 0.041. The value of $\Delta S_{P,th}$ is found to be independent of l since the anisotropy is equally effective for all the multipoles. The observed data, however, shows dominant alignment only for $l = 2, 3$ multipoles. Hence we need some mechanism to suppress the anisotropic contribution in the remaining multipoles. This can be accomplished if the Universe quickly evolves into an isotropic de Sitter phase during inflation [39]. This mechanism is implemented in model III.

In model III, $\Delta S_{P,th}$ oscillates, with amplitude decreasing with l . We attempt to fit the power entropy for $l = 2, 3$ in this model by fixing the parameter

Figure 1: The power entropy as a function of l for model III. The results are shown for three different choices of parameters, σ' and $q = 2/(\eta_0 a_I \bar{H})$.

$q = 2/(\eta_0 a_I \bar{H})$ and determining $\sigma' = \sigma/a_I$ by minimizing square error. However we find that the best fit is driven to relatively large values of σ' , where the perturbation theory becomes unreliable. The largest perturbative contribution is obtained for the isotropic part of the power spectrum. Hence here we only give results by fixing the parameter $\sigma' = 1.0$. The results for $S_{P,th}$ as a function of l for $q = 0.8, 1.0, 1.2$ with $\sigma' = 1.0$ are shown in Fig. 1. The figure clearly shows the oscillations in $S_{P,th}$. We also find that it approaches $\log 3$ for large l , as expected. The root mean square error for $\sigma' = 1$ and $q = 0.8, 1.0, 1.2$ is found to be 0.058, 0.056 and 0.055 respectively. We postpone a more detailed fit, involving larger values of l and perhaps polarization data in order to obtain a global minima to future research. In Fig. 1 we notice that the anisotropic contribution becomes negligible beyond $l \approx 10$. This might be related to the observations that low multipoles lying in the range $2 \leq l \leq 11$, and not just $l = 2, 3$, show alignment with the quadrupole [42, 46].

6 Summary and Conclusions

We have studied three models of anisotropic inflation in order to explain the observed violation of isotropy in CMBR data. In models I and III, the Universe is anisotropic only during the very early stages of inflation and quickly evolves into a de Sitter space-time. In model II, the anisotropy is present throughout the period of inflationary expansion. In all these models we choose the preferred direction same as the principal axis of the CMBR $l = 2$ mode. This axis points roughly in the direction of the Virgo supercluster. Model I leads to

direct correlations between multipoles l and $l + 1$. Hence it leads to alignment between $l = 2, 3$. In models II and III, there is no direct correlation between l and $l + 1$ modes. However each multipole is affected such that its principal axis is aligned with the preferred axis of the model. Hence these models also lead to alignment of the principle axis corresponding to $l = 2, 3$ multipoles. In models I and III, the anisotropic contribution affects dominantly the modes with low l . For higher l values, this contribution decays rapidly. Model II, in contrast, gives equal contribution to all l values.

We treat the anisotropic term perturbatively in all the three models. We compute the power spectrum and measures of alignment of $l = 2, 3$ multipoles at first order in perturbation theory. The measures of alignment use the concept of the power tensor [9, 42]. The three eigenvectors of this tensor define a frame in real space for each l . The eigenvector corresponding to the largest eigenvalue defines the principal axis. In models II and III the principal axis of both $l = 2, 3$ are aligned with the chosen preferred axis in these models and hence are aligned with one another. In model II we fix the theoretical parameters by fitting the dispersion in eigenvalues in $l = 2, 3$ modes. In model I, the anisotropic term does not contribute to the power tensor for any individual value of l . However it leads to a correlation between l and $l + 1$ modes. We define a new statistic, which tests the overall correlation of the power tensor between two adjacent modes. The theoretical estimate of this statistic is fitted to the observed data for $l = 2, 3$ modes. We find that models I and III provide a better description of data since they capture the important feature that the anisotropy decays rapidly for large l . We also find that perturbation theory is qualitatively reliable in models I and II. The contribution due to higher order terms in model I is likely to introduce a correction of about 25%. In model III, the best fit to the eigenvalue dispersion for $l = 2, 3$ modes is driven to relatively large values of the anisotropy parameter, making perturbation theory unreliable. In any case this might not be the best method to fix the model parameters since the dispersion observed in data is not statistically significant for these modes. Hence it may be better to fix the parameters of both models II and III by making a global fit to the CMBR temperature and polarization data. It may also be useful to perform a non-perturbative analysis of the anisotropic metrics.

The observed data has shown several signals which indicate a preferred direction, pointing roughly towards the Virgo supercluster. The fact that several diverse data sets, including radio, CMBR and optical, lead to the same preferred direction gives us some confidence that the observed anisotropy arises due to a physical effect. We have related these observations to an early anisotropic phase of inflation. It would clearly be of interest to test our models further by studying their implications for higher multipoles, CMBR polarization, radio and optical polarizations and the large scale structure of Universe.
